$$b_1 = \frac{(\sum x_2^2)(\sum x_1y) - (\sum x_1x_2)(\sum x_2y)}{(\sum x_1^2)(\sum x_2^2) - (\sum x_1x_2)^2} = 5.51$$

$$b_2 = \frac{(\sum x_1^2)(\sum x_2y) - (\sum x_1x_2)(\sum x_1y)}{(\sum x_1^2)(\sum x_2^2) - (\sum x_1x_2)^2} = 1.55$$

$$a = \bar{Y} - b_1\bar{X}_1 - b_2\bar{X}_2 = 325.77$$

$$Y = 325.77 + 5.51x_1 + 1.55x_2$$

$$\text{MSE} = \frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 = 10224.92$$

From the MSE and the predicted value we can conclude that the model is underfitted because the predicted linear model result is not much different from the mean which defeat the purpose of modelling itself.
